

Pointwise Convergence of Wavelet Expansions*

Susan E. Kelly [†] Mark A. Kon [‡] Louise A. Raphael [§]

Abstract

In this note we announce that under general hypotheses, wavelet-type expansions (of functions in L^p , $1 \leq p \leq \infty$, in one or more dimensions) converge pointwise almost everywhere, and identify the Lebesgue set of a function as a set of full measure on which they converge. It is shown that unlike the Fourier summation kernel, wavelet summation kernels P_j are bounded by radial decreasing L^1 convolution kernels. As a corollary it follows that best L^2 spline approximations on uniform meshes converge pointwise almost everywhere. Moreover, summation of wavelet expansions is partially insensitive to order of summation.

We also give necessary and sufficient conditions for given rates of convergence of wavelet expansions in the sup norm. Such expansions have order of convergence s if and only if the basic wavelet ψ is in the homogeneous Sobolev space $H_h^{-s-d/2}$. We also present equivalent necessary and sufficient conditions on the scaling function. The above results hold in one and in multiple dimensions.

1 Introduction

In this note we present several convergence results for wavelet and multiresolution-type expansions. It is natural to ask where such expansions converge (and whether they converge almost everywhere), and what are the rates of convergence. The answer is that under rather weak hypotheses, one- and multidimensional wavelet expansions converge pointwise almost everywhere, and more specifically on the Lebesgue set of a function being expanded. We will also give exact rates of convergence in the supremum norm, in terms of Sobolev properties of the basic wavelet or of the scaling function.

[§]Research partially supported by the Air Force Office of Scientific Research

Wavelets with local support in the time and frequency domains were defined by A. Grossman and J. Morlet [GM] in 1984 in order to analyze seismic data. The prototypes of wavelets, however, can be found in the work of A. Haar [Ha] and the modified Franklin systems of J.-O. Strömberg [St].

To identify the underlying structure and to generate interesting examples of orthonormal bases for $L^2(\mathbf{R})$, S. Mallat [Ma] and Y. Meyer developed the framework of multiresolution analysis. P.G. Lemarié and Y. Meyer [LM] constructed wavelets in $\mathcal{S}(\mathbf{R}^n)$, the space of rapidly decreasing smooth functions. J.-O. Strömberg [St] developed spline wavelets while looking for unconditional bases for Hardy spaces. G. Battle [Ba] and P.G. Lemarié [Le] developed these bases in the context of wavelet theory. Spline wavelets have exponential decay, but only C^N smoothness (for a finite N depending on the order of the associated splines). I. Daubechies [Da1] constructed compactly supported wavelets with C^N smoothness. The support of these wavelets increased with the smoothness; in general, to have C^∞ smoothness, wavelets must have infinite support.

Y. Meyer [Me] was among the first to study convergence results for wavelet expansions; he was followed by G. Walter ([Wa1], [Wa2]). Meyer proved that under some regularity assumptions on the wavelets, wavelet expansions of continuous functions converge everywhere. In contrast to these results, the pointwise convergence results presented here give almost everywhere convergence (and convergence on the Lebesgue set) for expansions of general L^p ($1 \leq p \leq \infty$) functions. We assume rather mild bounds and no differentiability for the wavelet or the scaling function; our conditions allow inclusion of the families of so-called r -regular wavelets [Me], as well as some other wavelets.

These results parallel L. Carleson [Ca] and R.A. Hunt's [Hu] theorems for Fourier series. One difference and slight advantage of wavelet expansions comes from the fact that almost everywhere convergence occurs on a simple set of full measure, namely the Lebesgue set, while almost everywhere convergence for Fourier series is established on a much more elaborate set of full measure.

We also give necessary and sufficient conditions for given pointwise (sup-norm) rates of convergence of wavelet or multiresolution expansions, in terms of Sobolev conditions on the basic wavelet or the scaling function. It has been shown previously by Mallat [Ma] and Meyer [Me] that the Sobolev class of a function is determined by the L^2 rates of convergence of its wavelet expansion. Necessary and sufficient conditions for L^2 rates of convergence which are analogous to our sup-norm conditions have been obtained by de Boor, DeVore, and Ron [BDR], who have also studied sup-norm convergence in more general situations [BR].

Our results on convergence rates can be viewed as a sharpening in the context of wavelets of the well-known Strang-Fix [SF] conditions for convergence of multiscale expansions.

The results given here hold for multiresolution expansions in multiple dimension. The proofs, which will appear elsewhere [KKR], involve the kernels of the

partial sums of such expansions, and the above mentioned result that such kernels are bounded by rescalings of L^1 radial functions. We should add that such bounds for wavelet expansions are non-trivial and arise from cancellations which occur in the sum representations of the partial sum kernels. Naive bounding of the summation kernels by using absolute values in their sum representations fails to yield the needed radial bounds for any class of wavelets. We remark that such bounds on the summation kernel can be obtained more easily by writing it using the orthonormal translates $\phi(x - k)$ of the scaling function, instead of the wavelets ψ_{jk} . However, in proving results for convergence of wavelet expansions (Theorem 2.1(iii)), we wish to avoid making any assumptions about radial bounds for the scaling function.

The pointwise and L^p convergence results contained here were obtained independently by the first author and by the second two authors. Results on the Gibbs effect obtained by the first author will appear elsewhere.

To start, we define a multiresolution analysis on $L^2(\mathbf{R}^d)$, ([Ma],[Me]).

Definition 1.1 *A multiresolution analysis on $L^2(\mathbf{R}^d)$, $d \geq 1$, is an increasing sequence $\{V_j\}_{j \in \mathbf{Z}}$,*

$$\dots \subset V_{-2} \subset V_{-1} \subset V_0 \subset V_1 \subset V_2 \subset \dots$$

of closed subspaces in $L^2(\mathbf{R}^d)$ where

$$\bigcap_{j \in \mathbf{Z}} V_j = \{0\}, \quad \overline{\bigcup_{j \in \mathbf{Z}} V_j} = L^2(\mathbf{R}^d),$$

and the spaces V_j satisfy the following additional properties:

(i) For all $f \in L^2(\mathbf{R}^d)$ and $j \in \mathbf{Z}$ and $k \in \mathbf{Z}^d$,

$$f(x) \in V_j \iff f(2x) \in V_{j+1}$$

and

$$f(x) \in V_0 \iff f(x - k) \in V_0.$$

(ii) There exists a scaling function $\phi \in V_0$ such that $\{\phi_{jk}\}_{k \in \mathbf{Z}^d}$ is an orthonormal basis of V_j , where

$$\phi_{jk}(x) = 2^{jd/2} \phi(2^j x - k), \tag{1}$$

for $x \in \mathbf{R}^d$ and $j \in \mathbf{Z}$ and $k \in \mathbf{Z}^d$.

Associated with the V_j spaces, we additionally define W_j to be the orthogonal complement of V_j in V_{j+1} , so that $V_{j+1} = V_j \oplus W_j$. Thus, $L^2(\mathbf{R}^d) = \overline{\sum \oplus W_j}$. We define P_j and $Q_j = P_{j+1} - P_j$, respectively, to be the orthogonal projections onto the spaces V_j and W_j , with kernels $P_j(x, y)$ and $Q_j(x, y)$.

Under the assumptions in the above definition, it can be proved ([Me], [Da2]) that there then exists a set $\{\psi^\lambda\} \in W_0$, where λ belongs to an index set Λ of cardinality

$2^d - 1$, such that $\{\psi_{jk}^\lambda\}_{k \in \mathbf{Z}^d, \lambda}$ is an orthonormal basis of W_j , and thus $\{\psi_{jk}^\lambda\}_{j \in \mathbf{Z}, k \in \mathbf{Z}^d, \lambda}$ is a *wavelet basis* of $L^2(\mathbf{R}^d)$, where

$$\psi_{jk}^\lambda(x) = 2^{jd/2} \psi^\lambda(2^j x - k), \quad (2)$$

for $x \in \mathbf{R}^d$, $j \in \mathbf{Z}$, and $k \in \mathbf{Z}^d$.

Definition 1.2 For $f \in L^p(\mathbf{R}^d)$ ($1 \leq p \leq \infty$) we define the following related expansions:

(a) The sequence of projections $\{P_j f(x)\}_j$ will be called the multiresolution expansion of f .

(b) The scaling expansion of f is defined to be

$$f \sim \sum_k b_k \phi(x - k) + \sum_{j \geq 0; k; \lambda} a_{jk} \psi_{jk}^\lambda(x), \quad (3)$$

where the coefficients a_{jk} and b_k are the L^2 expansion coefficients of f .

(c) The wavelet expansion of f is

$$f \sim \sum_{j; k; \lambda} a_{jk} \psi_{jk}^\lambda(x), \quad (4)$$

where the coefficients a_{jk} are the L^2 expansion coefficients of f .

We remark for part (a) of the above definition that it can be shown that the projections P_j (defined by their integral kernels) extend to bounded operators on L^p , $1 \leq p \leq \infty$. The L^2 expansion coefficients in (b) and (c) (defined by integration against f) are defined and uniformly bounded for any $f \in L^p$, $1 \leq p \leq \infty$.

Definition 1.3 The point x is a Lebesgue point of the measurable function $f(x)$ on \mathbf{R}^d if f is integrable in some neighborhood of x , and

$$\lim_{\epsilon \rightarrow 0} \frac{1}{V(B_\epsilon)} \int_{B_\epsilon} |f(x) - f(x + y)| dy = 0,$$

where B_ϵ denotes the ball of radius ϵ about the origin, and V denotes volume.

Such points p are essentially characterized by the fact that the average values of $f(x)$ around p converge to the values of f at these points, as averages are taken over smaller balls centered at x . Note that all continuity points are Lebesgue points, but the converse is not true.

Definition 1.4 A function $f(x)$ is in the class \mathcal{RB} if it is absolutely bounded by an L^1 radial decreasing function $\eta(x)$, i.e., $\eta(x_1) = \eta(x_2)$ whenever $|x_1| = |x_2|$, and $\eta(x_1) \leq \eta(x_2)$ when $|x_1| \geq |x_2|$, and $\eta(x) \in L^1(\mathbf{R}^d)$.

A function f is partially continuous if there exists a set A of vectors $a \in \mathbf{R}^d$ with positive measure such that $\lim_{\epsilon \rightarrow 0} \psi(x + \epsilon a) = \psi(x)$ for $a \in A$.

Definition 1.5 *The homogeneous Sobolev space of order s is defined by*

$$H_h^s \equiv \{f \in L^2(\mathbf{R}^d): \|f\|_{h,s} \equiv \sqrt{\int |\hat{f}(\xi)|^2 |\xi|^{2s} d\xi} < \infty\}. \quad (5)$$

The ordinary Sobolev space H^s is defined as H_h^s in (5), with replacement of $|\xi|^{2s}$ by $(|\xi|^{2s} + 1)$. Under the Fourier transform, the space H_h^s is a dense subspace of the complete weighted L^2 space of all measurable $\hat{f}(\xi)$ with $\|f\|_{h,s} < \infty$. This dense subspace consists of those functions $\hat{f}(\xi)$ which are also in the regular unweighted L^2 space.

Convergence rates of wavelet expansions are sensitive to both the smoothness of the wavelet and the smoothness of the function being expanded. For a wavelet ψ of given smoothness, the sensitivity to the Sobolev space of the function being expanded disappears when the function's Sobolev parameter is sufficiently large.

Definition 1.6 *A family ψ^λ of wavelets yields pointwise order of approximation (or pointwise order of convergence) r in the space H^s if for any function $f \in H^s$, the j^{th} order wavelet approximation $P_j f$ satisfies*

$$\|P_j f - f\|_\infty = O(2^{-jr}), \quad (6)$$

as j tends to infinity. More generally, the wavelets ψ^λ yield pointwise order of approximation (or convergence) r if for any function f which is sufficiently smooth (i.e., is in a Sobolev space of sufficiently large order s), (6) holds.

We will give several necessary and sufficient conditions (in terms of their Fourier transforms and membership in homogeneous Sobolev spaces) on the basic wavelet ψ or the scaling function ϕ for given orders of convergence. In practice, sufficient smoothness for a function f (in the sense of the above definition) will mean that f is in $H^{s+d/2}$ or a higher Sobolev space.

2 Pointwise Convergence Results

With the background given, our main results can now be presented.

Theorem 2.1 *(i) Assume only that the scaling function ϕ of a given multiresolution analysis is in \mathcal{RB} , i.e. that it is bounded by an L^1 radial decreasing function. Then for any $f \in L^p(\mathbf{R}^d)$ ($1 \leq p \leq \infty$), its multiresolution expansion $\{P_j f\}$ converges to f pointwise almost everywhere.*

(ii) If $\phi, \psi^\lambda \in \mathcal{RB}$ for all λ , then also both the scaling (3) (if $1 \leq p \leq \infty$) and wavelet (4) (if $1 \leq p < \infty$) expansions of any $f \in L^p$ converge to f pointwise almost everywhere. If further ψ^λ and ϕ are (partially) continuous, then both expansions converge to f on its Lebesgue set.

(iii) If we assume only $\psi^\lambda(x) \ln(2 + |x|) \in \mathcal{RB}$ for all λ , then for $f \in L^p$, its wavelet (for $1 \leq p < \infty$) and multiresolution (for $1 \leq p \leq \infty$) expansions converge to f pointwise almost everywhere. If further ψ^λ is (partially) continuous for all λ , then both the wavelet and multiresolution expansions converge to f on its Lebesgue set.

(iv) The last two statements hold for any order of summation in which the range of the values of j for which the sum over k and λ is partially complete always remains bounded.

In statement (iv) above, the summation over k and λ is *partially complete* for a fixed j if it contains some terms, but not all with the given value of j . By the *range of values* for which the sum is partially complete we mean the difference of the largest and smallest value of j for which the sum is partially complete. Statement (iv) requires that this range always be smaller than some constant M .

The above result on convergence of multiresolution expansions applies to spline expansions as well. Given a uniform grid K in \mathbf{R} , one might ask whether given a function $f \in L^2(\mathbf{R}^d)$, the best L^2 approximations $P_j f$ of f (by splines of a fixed polynomial order k) converge to f pointwise as the grid size goes to 0. The answer to this is affirmative.

Corollary 2.2 *For $f \in L^p(\mathbf{R})$ ($1 \leq p \leq \infty$), the order k best L^2 spline approximations $P_j f$ of f converge to f pointwise almost everywhere, and more specifically on the Lebesgue set of f , as the uniform mesh size goes to 0.*

The proof follows from the fact that best spline approximations are partial sums of multiresolution expansions, with some radially bounded (\mathcal{RB}) scaling function ϕ . This result also extends to multidimensional splines. Technically, the best L^2 approximation of $f \in L^p$ only makes sense when $p = 2$, but it can be defined for functions in L^p by continuous extension of the projections P_j from L^2 to L^p .

The following Theorem is a consequence of the proof of Theorem 2.1. It has been proved before under somewhat stronger hypotheses, yielding stronger conclusions in [Me].

Proposition 2.3 *Under the hypotheses of case (i), case (ii), or case (iii) of Theorem 2.1, L^p convergence of the expansions also follows for $1 \leq p < \infty$.*

Thus for wavelet series and more generally for one and multidimensional multiresolution expansions, essentially all hoped for convergence properties hold, regardless of rates of convergence.

The basis for Theorem 2.1 is the bound on the kernel of the projection P_j onto the scaling space V_j . It can be shown that under any of the hypotheses in Theorem 2.1, the kernel $P_m(x, y)$ has the form

$$P_m(x, y) = \sum_{j < m; k \in \mathbf{Z}^d; \lambda} \psi_{jk}^\lambda(x) \overline{\psi_{jk}^\lambda(y)} = \sum_{k \in \mathbf{Z}} \phi_{mk}(x) \overline{\phi_{mk}(y)}$$

for $x, y \in \mathbf{R}^d$, with convergence of both sums on the right occurring pointwise, uniformly on subsets a positive distance away from the diagonal $D = \{(x, y) : x = y\}$. The kernel converges to a delta distribution $\delta(x - y)$ in the following sense:

Theorem 2.4 *Under the assumption that $\phi \in \mathcal{RB}$ or that $\psi^\lambda(x) \ln(2 + |x|) \in \mathcal{RB}$ for all λ , the kernels $P_j(x, y)$ of the projections onto V_j satisfy the convolution bound*

$$|P_j(x, y)| \leq C2^{jd}H(2^j(|x - y|)), \quad (7)$$

where $H(|\cdot|) \in \mathcal{RB}$, i.e., $H(|\cdot|)$ is a radial decreasing L^1 function.

In one dimension, precise bounds can be obtained for kernels of specific wavelets. Two examples are illustrated in the result below.

Theorem 2.5 *In \mathbf{R}^1 , let $P_j(x, y) = \sum_{k \in \mathbf{Z}} \phi_{jk}(x)\phi_{jk}(y)$ be the summation kernel, generated by the scaling function $\phi \in L^2(\mathbf{R})$.*

(a) *If ϕ has exponential decay, i.e., $\phi(x) \leq Ce^{-a|x|}$ for some positive a , then*

$$|P_j(x, y)| \leq C2^j e^{-a2^j|x-y|/2}.$$

(b) *If ϕ has algebraic decay, $\phi(x) \leq \frac{C_N}{(1+|x|)^N}$ for some $N > 1$, then*

$$|P_j(x, y)| \leq C_N \frac{2^j}{(1 + 2^j|x - y|)^N} \leq C_N 2^j$$

for $N > 1$.

As a corollary, if a scaling function ϕ has rapid decay (faster than any polynomial), then $P_j(x, y)$ is bounded by a scaled convolution kernel (of the form on the right side of (7)) which has rapid decay. Spline wavelets (see [St], [Ba] and [Le]) satisfy the conditions in part (a), and wavelets constructed by P.G. Lemarie and Y. Meyer [LM] are an example of wavelets of rapid decay.

3 Rates of Convergence

We will now give necessary and sufficient conditions on the basic wavelet ψ^λ and on the scaling function ϕ , for given supremum-norm rates of convergence of wavelet expansions. The conditions on ψ^λ (here given in terms of membership in homogeneous Sobolev spaces) can be translated into differentiability and then moment conditions on ψ^λ (see introduction).

Theorem 3.1 *Given a multiresolution analysis with either (i) a scaling function $\phi \in \mathcal{RB}$, (ii) basic wavelets satisfying $\psi^\lambda \ln(2 + |x|) \in \mathcal{RB}$ for each λ , or (iii) a kernel for the basic projection P satisfying $|P(x, y)| \leq H(|x - y|)$ with $H \in \mathcal{RB}$, the following conditions ((a) to (e')) are equivalent:*

(a) *The multiresolution expansion (see Definition (1.2)) yields pointwise order of approximation s .*

(a') *The multiresolution expansion yields pointwise order of approximation s in every Sobolev space H^r for $r \geq s + d/2$.*

(b) *The projection $I - P_j: H_h^{s+d/2} \rightarrow L^\infty$ is a bounded operator, where I is the identity and d denotes dimension.*

If there exists a family $\{\psi^\lambda\}_\lambda \subset \mathcal{RB}$ of basic wavelets corresponding to $\{P_j\}$:

(c) *For every family of basic wavelets $\{\psi^\lambda\}_\lambda \subset \mathcal{RB}$ corresponding to $\{P_j\}$, and for each λ , $\psi^\lambda \in H_h^{-s-d/2}$.*

(d) *For every family of basic wavelets $\{\psi^\lambda\}_\lambda \subset \mathcal{RB}$ corresponding to $\{P_j\}$, and for each λ ,*

$$\int_{|\xi| < \epsilon} |\psi^\lambda(\xi)|^2 |\xi|^{-2(s+d/2)} d\xi < \infty \quad (8)$$

for some (or for all) $\epsilon > 0$.

(d') *For some family of basic wavelets $\{\psi^\lambda\}_\lambda \subset \mathcal{RB}$ corresponding to $\{P_j\}$, equation(8) holds.*

If in addition there exists a scaling function $\phi \in \mathcal{RB}$ corresponding to some family of basic wavelets as above:

(e) *For every such scaling function,*

$$\int_{|\xi| < \epsilon} \left((2\pi)^d |\hat{\phi}(\xi)|^2 - 1 \right) |\xi|^{-2(s+d/2)} d\xi < \infty \quad (9)$$

for some (or all) $\epsilon > 0$.

(e') *For some such scaling function ϕ , equation (9) holds.*

The above conditions on the scaling function can also be given in modified form in the case where the scaling function ϕ has non-orthonormal integer translates. Necessary and sufficient conditions for convergence rates of spline and other non-orthonormal expansions can then be obtained directly from the same arguments as above.

Acknowledgments: The authors wish to thank Guido Weiss for bringing us together. The first author would like to acknowledge that this work was done under the direction of Richard Rochberg and Mitchell Taibleson, and she thanks them for their guidance. The last two authors wish to thank Ingrid Daubechies, Bjorn Jawerth, Stephane Mallat, and Robert Strichartz for useful comments.
